COMPUTATIONAL ASPECTS OF CUI-FREEDEN STATISTICS
FOR EQUIDISTRIBUTION ON THE SPHERE

CHRISTINE CHOIRAT AND RAFFAELLO SERI

Abstract. In this paper, we derive the asymptotic statistical properties of a class of generalized discrepancies introduced by Cui and Freeden (SIAM J. Sci. Comput., 1997) to test equidistribution on the sphere. We show that they have highly desirable properties and encompass several statistics already proposed in the literature. In particular, it turns out that the limiting distribution is an (infinite) weighted sum of chi-squared random variables. Issues concerning the approximation of this distribution are considered in detail and explicit bounds for the approximation error are given. The statistics are then applied to assess the equidistribution of Hammersley low discrepancy sequences on the sphere and the uniformity of a dataset concerning magnetic orientations.

1. Introduction

The aim of this paper is to derive the properties of a new class of statistics for testing equidistribution on the sphere and to investigate their computational aspects. They have been introduced in a seminal paper by Cui and Freeden (see [10]) under the name of generalized discrepancies in order to extend the famous Koksma-Hlawka inequality of Numerical Analysis from the unit hypercube to the sphere, and to evaluate the uniformity properties of some deterministic sequences on the sphere. Some further properties of these discrepancies with direct interest for Numerical Analysis are developed in [43]. These discrepancies can be generalized to hyperspheres of arbitrary dimension: for the numerical properties in this case, the reader may consult [9].

These discrepancies are indicated in the following as $D(P_N; A)$ where $P_N$ is a sample of points and $A$ is a pseudodifferential operator acting on functions defined on the sphere $\Omega \subset \mathbb{R}^3$, that enters $D$ only through its symbol, that is a sequence of constants $\{A_n; n = 0, 1, \ldots\}$. In the following we will need no property of $A$ apart from its symbol. We address the reader interested in the mathematical details underlying the formulas to the original paper [10], in which the authors do not however derive the statistical properties of this class of discrepancies. This is the object of the present paper. A short exposition of the mathematical background necessary to understand the statistical results is given in Section 2. The test statistics encompass those of Beran ([4]), Giné ([21]), Prentice ([33], see also [34]),

1 The same name was used by Hickernell ([25]) to denote a different class of discrepancies on the unit hypercube, whose statistical properties were studied in [8].
and Pycke ([36, 37]). It is important to remark that some of these test statistics have particular optimality properties (e.g., against certain hypotheses) that are not shared by the general version $D(P_N; A)$. The definition of $D(P_N; A)$ is expressed in terms of a (generally infinite) sum and its computation may be unstable when no closed formula exists. For this reason, in Section 3 we review a set of cases in which closed formulas are available. The main statistical results are stated in Section 4: in particular, the asymptotic distribution of generalized discrepancies is shown to be an infinite weighted sum of chi-square random variables. The computation of this distribution passes customarily through the truncation of the infinite sum and its approximation through a finite weighted sum. Several methods are available to compute finite weighted sums of chi-squares (see [27, 14, 41, 15, 38], just to name a few), but the error caused by the truncation of the infinite sequence of weights is not sufficiently investigated in the literature. This is particularly relevant in this case, since the number of degrees of freedom of the chi-squares in the sum increases with the summation index. Therefore we provide some easily computable and effective bounds for the truncation error in Section 5. In Section 6, we consider a particular version of the statistic proposed in [10]; we evaluate through simulations the finite-sample performance of the statistic and the error in the approximation of the asymptotic distribution, and we use it to evaluate the uniformity of a deterministic sequence; at last, we compare several statistics on a dataset on $\Omega$. Proofs are gathered in Section 7.

2. Mathematical preliminaries

In order to introduce the formula of $D(P_N; A)$, we need some concepts from Functional Analysis on the sphere. Let $L^2(\Omega)$ be the space of Lebesgue square integrable scalar functions on $\Omega$. The spherical harmonics

$$\{Y_{n,j}; n = 0, 1, \ldots; j = -n, -n + 1, \ldots, n - 1, n\}$$

are a class of double indexed functions defined on $\Omega$, where $n$ is called the degree and $j$ is called the order of the spherical harmonics. Spherical harmonics constitute an orthonormal basis of $L^2(\Omega)$, when $\Omega$ is endowed with the Lebesgue measure. The Legendre polynomials $\{P_n; n = 0, 1, \ldots\}$ are the infinitely differentiable eigenfunctions of the Legendre operator satisfying the normalization condition $|P_n(1)| = 1$. The addition theorem of spherical harmonics links these functions to the Legendre polynomials through the relation:

$$\sum_{j = -n}^{n} Y_{n,j}(\xi) \cdot Y_{n,j}(\eta) = \frac{2n + 1}{4\pi} \cdot P_n(\xi \cdot \eta), \quad (\xi, \eta) \in \Omega^2,$$

where $\cdot$ denotes the inner product on the sphere. In particular, taking $\xi = \eta$, we have that $\sum_{j = -n}^{n} |Y_{n,j}(\xi)|^2 = \frac{2n + 1}{4\pi}$.

The only property of a pseudodifferential operator $A$ that we will need is the spherical symbol, that is a sequence $\{A_n; n = 0, 1, \ldots\}$ of real numbers characterizing the behavior of the operator. If $\lim_{n \to \infty} \frac{|A_n|}{(n + \frac{1}{2})^t} = \text{const} \neq 0$ for some $t \in \mathbb{R}$, then $A$ is a pseudodifferential operator of order $t$. If, on the other hand, $\lim_{n \to \infty} \frac{|A_n|}{(n + \frac{1}{2})^t} = 0$ for any $t \geq 0$, $A$ is of order $-\infty$. Since we are not interested in the way in which $A$ acts on functions defined on $\Omega$, but only in $\{A_n; n = 0, 1, \ldots\}$,

\footnote{Note that here we use the real-valued spherical harmonics and not the complex ones.}
for us the fact that $A$ is of order $t$ reduces to the rate of decrease of $A_n$ to 0 (however, see [10] p. 597, for more information).

Let $\mathcal{P}_N = \{\xi_1, \xi_2, \ldots, \xi_N\}$ be a set of points on $\Omega$. The generalized discrepancy associated with a pseudodifferential operator $A$ with symbol $\{A_n\}$, $A_n \neq 0$ for $n \geq 1$, is defined by

$$D(\mathcal{P}_N; A) = \frac{1}{N} \left[ \sum_{i=1}^{N} \sum_{j=1}^{N} \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(\xi_i \cdot \xi_j) \right]^{1/2}. \tag{2.1}$$

A difference with respect to the case considered in [10] is the fact that these authors suppose that $A_n$ is finite for every $n \geq 1$, while in statistical applications there is some interest in allowing for $A_n^{-1} = 0$ for some $n$, as we will show in the examples below.

In Section 3, we consider the computation of the test statistic. In Section 4, we will consider the asymptotic properties of $D^2(\mathcal{P}_N; A)$. The computation of the asymptotic distribution is addressed in Section 5, while Section 6 shows simulations providing support for the previous results.

3. COMPUTATION OF THE TEST STATISTICS

The computation of $D^2(\mathcal{P}_N; A)$ for a specific point set $\mathcal{P}_N$ is much more difficult than it seems. Indeed, the computation of the Legendre polynomials appearing in (2.1) can be overly complicated if a nonstable numerical formula for $P_n$ is used (see the introductory treatment in [35, Section 5.4]). This fact is noted also in [10, p. 602]. Therefore, it is always better to have a closed form expression for $\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(\xi \cdot \eta)$.

Some tests used in Statistics are characterized by explicit forms. Closed formulas trivially exist for the Rayleigh statistic $\frac{1}{N^2} \sum_{i=1}^{N} \sum_{j=1}^{N} P_1(\xi_i \cdot \xi_j)$ obtained taking $A_1 = \frac{3}{4\pi}$ and $A_n^{-1} = 0$ for $n \geq 2$ (see [21] p. 1263) and for the Bingham statistic $\frac{1}{N^2} \sum_{i=1}^{N} \sum_{j=1}^{N} P_2(\xi_i \cdot \xi_j)$ obtained taking $A_2 = \frac{5}{4\pi}$ and $A_n^{-1} = 0$ for $n \neq 2$ (see [21, p. 1264]). Other, more complicated cases are:

- Beran’s form of Ajne’s statistic (see [33] p. 172); note that [21] p. 1262] uses a different normalization):

$$\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = \frac{1}{4} - (2\pi)^{-1} \cos^{-1} t,$$

obtained taking $A_n^2 = +\infty$ for $n$ even and $A_n^2 = n^2 \cdot \left( \frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma\left(\frac{n+3}{2}\right)} \right)^2$ for $n$ odd (see, e.g., equation 8.925.1 in [22]),

- Giné’s statistic (see [21] p. 1262) and, in particular, Proposition 6.4):

$$\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = \frac{1}{2} - 2\pi^{-1} \sin^{-1} t,$$

obtained taking $A_n^2 = +\infty$ for $n$ odd and $A_n^2 = \frac{n-1}{n+2} \cdot \left( \frac{\Gamma\left(\frac{n}{2}\right)}{\Gamma\left(\frac{n+1}{2}\right)} \right)^2$ for $n$ even (see, e.g., equation 8.925.2 in [22]),
• and Pycke’s statistic (see [36, 37]):
\[ \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = -\frac{1}{4\pi} \cdot \ln \frac{e}{2} \cdot (1-t), \]

obtained taking \( A_n = \sqrt{n(n+1)} \) (see, e.g., equations 8.926.1 and 2 in [22]; however, note that this statistic does not respect the condition \( \sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} < \infty \), and has to be analyzed as in Theorem 4.1 (iv)).

In Numerical Analysis, the most prominent case arises when
\[ A_n = \sqrt{2n+1}, \]
yielding (see equations 8.926.1 and 2 in [22]):
\[ D^2 (P_N; A) = \frac{1}{N^2} \cdot \sum_{i=1}^{N} \sum_{j=1}^{N} \frac{1}{4\pi} \cdot \left[ 1 - 2 \ln \left( 1 + \sqrt{1 - \eta_i \cdot \eta_j} \right) \right]. \]

This is the case considered in [10, p. 598], [43] and [26] (where it is called D-discrepancy, see p. 6).

A closed form arises also when \( A_n = -n(n+1) \). In this case, described in detail in [20, Section 4.7], we have
\[ \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = \frac{1}{4\pi} \cdot \left\{ -\pi^2 - \frac{L_2\left(1 + \frac{t}{2}\right)}{6} \right\}, \]
where \( L_2(\cdot) \) is the so-called dilogarithm:
\[ L_2(u) = -\int_{0}^{u} \frac{\ln(1-v)}{v} \, dv = \sum_{k=1}^{\infty} \frac{u^k}{k^2}. \]
The formula appearing in [20] is slightly more complicated than the one above, which is taken from [24, p. 142]. We remark, in passing, that this is equal, up to multiplication by \( \frac{1}{4\pi} \), to (0.8) in [16], even if the formula in the last reference is even more complicated than those quoted above.

A case that has attracted a lot of interest arises if we consider the Riesz kernels (see, e.g., [11]), appearing in the analysis of \( s \)-energies ([30, 12]). For \( \xi_1, \xi_2 \in \Omega \), we define
\[ K(\xi_1, \xi_2) = \begin{cases} \text{sign}(s) \cdot \|\xi_1 - \xi_2\|_2^{-s}, & s \neq 0, \\ -\ln \|\xi_1 - \xi_2\|_2^2, & s = 0, \end{cases} \]
where \( \|\cdot\|_2 \) is the Euclidean distance. The choices \( s = 0 \) and \( s = 1 \) lead respectively to the logarithmic and Coulombic potential. We can write this kernel as \( K(\xi_1, \xi_2) = k_s(\xi_1 \cdot \xi_2) \), where
\[ k_s(t) = \begin{cases} \text{sign}(s) \cdot |2(1-t)|^{-\frac{s}{2}}, & s \neq 0, \\ -\ln 2(1-t), & s = 0, \end{cases} \]
for \( t \in [-1, 1] \). When \( s \neq 0 \), the choice
\[ A_n^2 = \frac{2^{s-2} \Gamma\left(\frac{s}{2}\right) \Gamma\left(-\frac{s}{2} + n + 2\right)}{\pi \Gamma\left(\frac{s}{2} + n\right) \Gamma\left(1 - \frac{s}{2}\right)}. \]
for \( s < 2 \) yields
\[
\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = |2(1-t)|^{-\frac{s}{2}} - \frac{2^{-s}}{1 - \frac{s}{2}} = \text{sign} (s) \cdot k_s(t) - \frac{2^{-s}}{1 - \frac{s}{2}}.
\]
When \( s = 0 \), the choice
\[
A_n^2 = \frac{n(n+1)}{4\pi}
\]
yields
\[
\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = -\ln 2 (1-t) - \ln \frac{e}{4} = k_0(t) - \ln \frac{e}{4}.
\]
This is simply a version of Pycke’s statistic.

Note that \( A_n^2 \sim n^{-s+2} \), so that \( \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \sim \sum_{n=1}^{\infty} n^{s-1} \), and this converges if \( s < 0 \). Therefore the \( D^2(\mathcal{P}_N;A) \) form of the discrepancy can be used only when \( s < 0 \). On the other hand, \( d^2(\mathcal{P}_N;A) \) (see Theorem 4.1(iv) below) can be used if \( \sum_{n=1}^{\infty} \left( \frac{2n+1}{4\pi A_n^2} \right)^2 \sim \sum_{n=1}^{\infty} n^{2s-2} \) converges: this holds if \( s < \frac{1}{2} \).

The requirement that \( s < 2 \) is quite unfortunate. Generalized Riesz kernels remove it (see [13, p. 817]). In [5, Appendix B], some computations are available that allow one to recover \( A_n^2 \) for \( s > 0 \) in the case of generalized Riesz kernels.

Some new cases can be obtained from the mathematical literature on special functions. When \( A_n^2 = (2n+1) \cdot \rho^{-n} \) for \( \rho \in (-1,1) \), the generating function of Legendre polynomials yields (see [39, p. 533] for a more general formula):
\[
\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = \frac{1}{4\pi} \frac{1}{(1-2\rho t + \rho^2)^{1/2}} - \frac{1}{4\pi}.
\]
while when \( A_n^2 = \rho^{-n} \) for \( \rho \in (0,1) \) we get the Abel-Poisson kernel (see [39, p. 534]):
\[
\sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n(t) = \frac{1}{4\pi} \frac{1 - \rho^2}{(1-2\rho t + \rho^2)^{3/2}} - \frac{1}{4\pi}.
\]
Other situations in which closed form expressions exist are given in [16, pp. 41-42] and [24], but not all of them respect the condition \( \sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} < \infty \) (see Theorem 4.1).

4. ASYMPTOTIC PROPERTIES

The following theorem provides the most relevant asymptotic properties of the generalized discrepancies under the null hypothesis of uniform distribution of the sample of points \( \mathcal{P}_N \).

**Theorem 4.1.** Let \( \mathcal{P}_N \) be a sample of iid uniform random variables on \( \Omega \), and suppose that the spherical symbol \( \{A_n\} \) of the pseudodifferential operator \( A \) is such that \( A_n \neq 0 \) for any \( n \). Then, if \( \sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} < \infty \) the first three properties hold.

(i) \( D^2(\mathcal{P}_N; A) \xrightarrow{\text{as}} 0. \)

(ii) \( N \cdot D^2(\mathcal{P}_N; A) \xrightarrow{\mathcal{D}} \sum_{n=1}^{\infty} \frac{1}{4\pi A_n^2} \cdot \chi^2_n(2n+1), \)
where $\chi^2(k)$ denotes a $\chi^2$ random variable with $k$ degrees of freedom, and 
\(\{\chi^2_n (2n+1) \; ; \; n \in \mathbb{N}\}\) is a sequence of independent $\chi^2$ random variables.

(iii) The following uniform bound holds:

\[
\left| \mathbb{P} \left\{ N \cdot D^2 \leq y \right\} - \mathbb{P} \left\{ \sum_{n=1}^{\infty} \frac{\chi_n^2 (2n+1)}{4\pi A_n^2} \leq y \right\} \right| 
\leq e^{-\lambda_{13}} \sqrt{\sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} \cdot \left( 1 + \left( \frac{\sum_{n=1}^{\infty} \frac{2n+1}{A_n^2}}{\frac{2}{3}} \right)^{\frac{3}{2}} \right)}
\]

where $\lambda_{13}$ is defined in the proof of the theorem.

(iv) If $\sum_{n=1}^{\infty} \left( \frac{2n+1}{A_n^2} \right)^2 < \infty$, the modified statistic

\[
d^2 (P_N; A) = \frac{1}{N^2} \sum_{i \neq j=1}^{N} \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n (\xi_i \cdot \xi_j)
\]

obtained removing the diagonal elements is such that $d^2 (P_N; A) \xrightarrow{as} 0$ and

\[
N \cdot d^2 (P_N; A) \xrightarrow{D} \sum_{n=1}^{\infty} \frac{1}{4\pi A_n^2} \cdot \left[ \chi_n^2 (2n+1) - (2n+1) \right].
\]

Remark 1. (i) When $A_n = \sqrt{(2n+1) \cdot n (n+1)}$, \(\sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} = \sum_{n=1}^{\infty} \frac{1}{\pi(n+1)} = 1 < \infty\) and

\[
N \cdot D^2 (P_N; A) \xrightarrow{D} \sum_{n=1}^{\infty} \frac{\chi_n^2 (2n+1)}{4\pi (2n+1) \cdot n (n+1)}.
\]

When $A_n^2 = \rho^{-n}$, then $N \cdot D^2 (P_N; A) \xrightarrow{D} \frac{1}{4\pi} \sum_{n=1}^{\infty} \rho^n \cdot \chi_n^2 (2n+1)$. When $A_n = \sqrt{n \cdot (n+1)}$ (i.e., Pycke’s statistic), we have to use the statistic $d^2$ and we get

\[
N \cdot d^2 (P_N; A) \xrightarrow{D} \sum_{n=1}^{\infty} \frac{\chi_n^2 (2n+1) - (2n+1)}{4\pi n (n+1)}.
\]

(ii) If $A$ is such that $k_1 \cdot n^{1+\alpha} \leq A_n \leq k_2 \cdot n^{1+\alpha}$ for $\alpha > 0$ and $0 < k_1 \leq k_2 < +\infty$, then the bound has the following behavior in terms of $N$ and $\alpha$:

\[
\left| \mathbb{P} \left\{ N \cdot D^2 \leq y \right\} - \mathbb{P} \left\{ \sum_{n=1}^{\infty} \frac{\chi_n^2 (2n+1)}{4\pi A_n^2} \leq y \right\} \right| 
\leq e^{-\zeta(3+4\alpha)} \sqrt{\zeta(3+4\alpha)} \cdot \left( 1 + \frac{\zeta^{\frac{3}{2}} \left( 1 + 2\alpha \right)}{\zeta^{\frac{3}{2}} \left( 3 + 4\alpha \right)} \right)
\]

where $\zeta$ is the Riemann zeta function. The only practical implication of $\alpha$ is in the exponent; this shows that a large value of $\alpha$ implies a worse convergence rate.

(iii) Adapting Theorem 4.4 in [21], it is possible to show the following fact: The condition $A_n^2 < +\infty$ for any $n$ is equivalent to the fact that $D^2 (P_N; A) \xrightarrow{P} 0$ iff the sample $P_N$ comes from a uniform distribution. This implies that a test based on a generalized discrepancy may converge to 0 also for nonuniform distributions if $A_n^2 = +\infty$ for some $n$. As an example, Gine’s statistic (which has $A_n^2 = +\infty$ for $n$ odd, see above) converges to 0 for every probability measure uniform on the projective space and not only on the sphere (see [21] p. 1262)].
As concerns the asymptotic properties under the alternative hypothesis that the points are independent realizations of a nonuniform distribution, we just quote them, together with references to results in the literature that allow for deriving them. Consider an iid sample $\mathcal{P}_N^\star$ drawn from a distribution $\mathbb{P}^\star$ on the sphere different from the uniform distribution. Note that, according to Remark \(\text{i}(\text{iii})\), if $A_n^2 = +\infty$ for some $n$, then $D^2 (\mathcal{P}_N^\star; A)$ can converge in probability to 0 even if the sample $\mathcal{P}_N^\star$ does not come from a uniform distribution. The following properties hold if $D^2 (\mathcal{P}_N^\star; A)$ does not converge in probability to 0. Using Corollary 4 of \([1, \text{p. 5}]\), it is possible to show that when $D^2 (\mathcal{P}_N^\star; A)$ is suitably centered and scaled, it converges in distribution to a standard normal random variable. A uniform bound on the distance between the finite sample and the asymptotic distribution can be obtained through \([1, \text{Corollary 5, p. 5}]\) and decreases as $1/\sqrt{N}$. The asymptotic distribution of $N \cdot D^2 (\mathcal{P}_N^\star; A)$ under a local alternative converging to the null, i.e., under a Pitman drift, is given by a weighted sum of noncentral $\chi^2$ random variables (see \([23, \text{Theorem 2.1}]\)).

5. Computation of the asymptotic distribution

In this section, we consider approximations of the asymptotic distribution of $N \cdot D^2 (\mathcal{P}_N; A)$, denoted, in the following as $X = \sum_{n=1}^{\infty} \frac{\chi_n^2(2n+1)}{4\pi A_n^2}$, through three different methods. This topic is relevant for any distribution given by a weighted sum of $\chi^2$ random variables, but is particularly critical here. Indeed, contributions to $X$ corresponding to large values of $n$ (that is $\frac{\chi_n^2(2n+1)}{4\pi A_n^2}$) can be quite relevant since the degrees of freedom of the $\chi^2$ random variable depend on $n$ (this problem does not arise with the most common test statistics on the real line, such as Cramér-von Mises and Anderson-Darling, and is a facet of the curse of dimensionality problem).

The first approximation amounts to considering a scaled and translated $\Gamma$ distributed random variable $X_{\Gamma}$ that matches the first three moments of $X$:

$$X_{\Gamma} = \mu + \frac{\Gamma (\nu/2, 2) - \nu}{\sqrt{2\nu}} \cdot \sigma$$

where $\Gamma (\alpha, \theta)$ denotes a $\Gamma$ random variable with shape parameter $\alpha$ and scale parameter $\theta$,

$$\mu = \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2}, \quad \sigma^2 = 2 \sum_{n=1}^{\infty} \frac{2n+1}{(4\pi A_n^2)^2}$$

and

$$\nu = \left( \sum_{n=1}^{\infty} \frac{2n+1}{A_n^2} \right)^3 / \left( \sum_{n=1}^{\infty} \frac{2n+1}{A_n^6} \right)^2.$$

This approximation for linear combinations of $\chi^2$ random variables has been considered in \([6]\), in \([31]\) and in \([46]\), where uniform bounds are also derived.

We propose also the following truncated version of $X$:

$$X_{\nu} = \sum_{n=1}^{\nu} \frac{\chi_n^2(2n+1)}{4\pi A_n^2}.$$ 

We will show that a better alternative is to use a centered version of $X_{\nu}$:

$$X_{\nu}^* = \sum_{n=1}^{\nu} \frac{\chi_n^2(2n+1)}{4\pi A_n^2} + \sum_{n=\nu+1}^{\infty} \frac{2n+1}{4\pi A_n^2}.$$
The computation of $X_\nu$ can then be easily performed using the algorithm described in [13] and linked in R from C in [7]. We majorize the errors implied by the replacement of $X$ with $X_\nu$ or $X^*_\nu$ using the following bounds.

**Theorem 5.1.** We have:

$$|\mathbb{P}\{X \leq x\} - \mathbb{P}\{X_\nu \leq x\}| \leq \sqrt{\frac{2}{\pi \sqrt{3}} \cdot \frac{2}{\nu} \cdot B\left(\frac{1}{2}, \frac{1}{4}\right)} \cdot \frac{\nu}{\pi}.$$  

and

$$|\mathbb{P}\{X \leq x\} - \mathbb{P}\{X^*_\nu \leq x\}| \leq \frac{\nu^2}{\alpha} \cdot \frac{\sqrt{3}}{16\pi^2} \cdot B\left(\frac{1}{2}, \frac{1}{4}\right) \cdot (1 + o(1),$$

where $\sigma^2$ has been defined above.

**Remark 2.** (i) Both bounds are tight, as will be shown in Section 6.

(ii) The previous bounds assert that the approximation of $X$ through $X_\nu$ and $X^*_\nu$ is better when the order of the pseudodifferential operator $A$ is higher. This is in line with [10, p. 602], where it is stated that computation of $D^2(\mathcal{P}_N; A)$ is easier the larger $t$ is.

(iii) For the interesting case $A_n = \sqrt{2n+1} n(n+1)$, we have $k = 1/\sqrt{2}$ and $\alpha = 1/2$, so that

$$|\mathbb{P}\{X \leq x\} - \mathbb{P}\{X_\nu \leq x\}| \leq \frac{\nu^2}{\alpha} \cdot \frac{\sqrt{3}}{16\pi^2} \cdot B\left(\frac{1}{2}, \frac{1}{4}\right) \cdot (1 + o(1),$$

where $X^*_\nu = X_\nu + \frac{1}{4\pi(\nu+1)}$. Even if the constant of the second bound is quite large, the bound shows that the approximation is very good even for small values of $\nu$. When $A_n^2 = (2n+1) \cdot \rho^{-n}$, the first bound is $O(\rho^{2\nu})$ while the second is $O(\rho^{4\nu})$; when $A_n^2 = \rho^{-n}$, the former is $O(\rho^{3\nu})$ while the latter is $O(\rho^{5\nu})$.

(iv) When using the statistic $d^2(\mathcal{P}_N; A)$, centering is automatic and only the second bound applies.

6. **Simulation results and applications**

In this section we deal with four distinct topics, namely the rate of convergence of the finite-sample distribution of $N \cdot D^2(\mathcal{P}_N; A)$ to the asymptotic one, the accuracy of the approximations $X_T$, $X_\nu$ and $X^*_\nu$ to $X$, the use of our asymptotic results to
evaluate the quality of quasi-Monte Carlo sequences on the sphere, and at last a statistical application to magnetic orientations.

When not explicitly stated otherwise, we consider only the Cui-Freeden test statistic $N \cdot D^2(P_N; A)$ for $A_n = \sqrt{(2n + 1) n (n + 1)}$, since in this case a closed form expression exists and the previously quoted topics can be investigated without further problems arising in the computation of the test statistic through Legendre polynomials.

### 6.1. Rate of convergence to the asymptotic distribution.

In Figure 1 we have reproduced the finite-sample cdf (say $F_N$) for $N \in \{10, 30, 100\}$ and the asymptotic cdf (say $F_\infty$). The finite-sample distributions are based on Monte Carlo sampling of $S = 10,000,000$ values of the test statistic $N \cdot D^2(P_N; A)$. In this case, the Laws of the Iterated Logarithm for the empirical cdf (see, e.g., [44, p. 268]) prescribe that (asymptotically) the maximal error in the Monte Carlo approximation of $F_N$ through 10,000,000 points is at most $0.0003728232$ and at least $0.0002106624$.

![Graphs showing the distribution of $N \cdot D^2(P_N; A)$ for $N = 10, 30, 100$ and $\infty$.](image)

**Figure 1.** Distribution of $N \cdot D^2(P_N; A)$ for $N = 10, 30, 100$ and $\infty$.

From the graphs it is not possible to devise any deviation of the finite-sample distributions from the asymptotic one. Therefore, in Figure 2 we have reproduced also the deviation $F_N - F_\infty$ between the finite-sample and the asymptotic distributions. It turns out that the convergence is indeed very fast and the error for $N = 10$ is around 0.015. The decrease in $1/N$ in the figure is coherent with the bound in Theorem 4.1.

### 6.2. Accuracy of approximations to the asymptotic distribution.

In Figure 3 we represent the deviation between the asymptotic distribution of $N \cdot D^2(P_N; A)$ and the proposed approximations. UNC-Real is the deviation $\sup_x |\mathbb{P}\{X \leq x\} - \mathbb{P}\{X^* \leq x\}|$, while CEN-Real is $\sup_x |\mathbb{P}\{X \leq x\} - \mathbb{P}\{X^* \leq x\}|$. UNC-Comp and CEN-Comp are the bounds computed through Theorem 5.1. It is possible to see that both UNC-Comp and CEN-Comp are precise upper bounds respectively on UNC-Real and CEN-Real. The most striking feature arising from the graph is the dramatic improvement in the performance of the approximation.
Figure 2. Deviation of the distribution of $N \cdot D^2 (P_N; A)$ for $N = 10, 30, 100$ with respect to the asymptotic one.

method that can be obtained simply through centering, even if this operation involves a shift of the distribution through a small constant such as $\sum_{n=\nu+1}^{\infty} \frac{2n+1}{4\pi A_n^2} = \frac{1}{4\pi(\nu+1)}$. Centering allows for a reduction of the error behavior from $\Theta (\nu^{-1})$ to $\Theta (\nu^{-4})$ as shown by Theorem 5.1.

From the previous figure, it seems that the $\Gamma$ approximation cannot compete with the other methods, but the use of a uniform bound hides the fact that for most quantiles of interest (confined to the upper tail) the $\Gamma$ approximation is extremely good. In Figure 3, the quantities $\mathbb{P} \{ X^*_{\nu} \leq x \} - \mathbb{P} \{ X \leq x \}$, $\mathbb{P} \{ X_{\nu} \leq x \} - \mathbb{P} \{ X \leq x \}$ and $\mathbb{P} \{ X_{\Gamma} \leq x \} - \mathbb{P} \{ X \leq x \}$ are shown for $\nu = 100$, that is when the errors in the approximation of $X$ through $X_{\nu}$ and $X_{\Gamma}$ are almost equal: this comparison shows that, while $X^*_{\nu}$ is by far the best method, $X_{\Gamma}$ approximates $X$ better than $X_{\nu}$ in the upper tail. The graph of the Gamma approximation is strikingly similar to the one in [6, p. 155].
6.3. Uniformity of quasi-Monte Carlo sequences. In this section, we show how generalized discrepancies can be used in the assessment of low-discrepancy (often called quasi-Monte Carlo) sequences.\(^3\)

We recall the definition of the Hammersley sequence in the two-dimensional hypercube and on the sphere (see [10, p. 605]). Let \( p \) be an integer greater than or equal to 2. Then any integer \( n \) can be expressed as \( n = a_0 + \cdots + a_r p^r \), for an integer \( r \) and positive or null integer coefficients \( a_0, \ldots, a_r \). The \( n \)th element of the \( p \)--adic van der Corput sequence is defined by \( x_n(p) = a_0 + \cdots + a_r p^r \). The Hammersley sequence of length \( N \) in the two-dimensional hypercube is defined by \((t_n, \phi_n)_{n=1,\ldots,N} = (\frac{2n-1}{2N}, x_n(p))_{n=1,\ldots,N} \). The Hammersley sequence on the sphere is defined by applying to each element of the sequence \((t_n, \phi_n)_{n=1,\ldots,N} \) the following transformation:

\[
(t, \phi) \mapsto \left( \sqrt{1 - (2t - 1)^2 \cos(2\pi \phi)} , \sqrt{1 - (2t - 1)^2 \sin(2\pi \phi)} , 2t - 1 \right) .
\]

In [45], the Hammersley sequence has been proposed for the solution of some problems in computer graphics. In particular, the authors remark that when \( p \) (in their paper denoted as \( p_1 \)) increases, the uniformity of the sequence seems to get worse:

Figures 2 and 3 show the Hammersley points with different bases, on the plane and the sphere respectively. When \( p_1 = 2 \), it gives the best uniformly distributed pattern on the sphere. Cui et al. [5] measures the uniformity of Hammersley points with \( p_1 = 2 \) on the sphere using the generalized discrepancy. It gives the lowest generalized discrepancy (most uniformly distributed) among the methods tested. As \( p_1 \) increases (from Figures 3(b) to 3(f)), points start to line up and form regular lines on the sphere. The position of the pole (marked with an arrow) becomes distinguishable from the pattern. [...] The Hammersley point set with \( p_1 = 2 \) gives the
most uniformly distributed sampling pattern. For higher $p_1$, the points tend to align and reduce its usefulness.

Here, we quantify the qualitative remark in [45]. Therefore, we have computed the value of $N \cdot D^2(P_N; A)$ when $P_N$ is a Hammersley sequence on the sphere for $N$ varying in the interval $[10, 10000]$ and for $p$ prime and comprised between 2 and 23 (the restriction to prime numbers is not necessary, but customary; see, e.g., [17, p. 28]). The results are represented in Figure 5: from this, it is evident that the sequence with $p = 2$, represented by the continuous line, is uniformly the best one. When $p$ increases, the generalized discrepancy $N \cdot D^2(P_N; A)$, represented by a dashed line, shows an oscillating behavior but remains consistently above the (black) curve with $p = 2$. By the way, this is coherent with the behavior of the star discrepancy of Hammersley sequences that can be shown to worsen when $p$ increases (see [32, Theorem 3.8]).

![Figure 5](image-url)

**Figure 5.** Values of $N \cdot D^2(P_N; A)$ when $P_N$ is an Hammersley sequence with varying values of $N$ (on the horizontal axis) and of $p$.

6.4. **A statistical example.** We have considered a classical dataset concerning 52 measurements of magnetic remanence from specimens of red beds from Bowen Basin, Queensland, after thermal demagnetisation to 670°C (see Table B5 in [18]). We have computed seven statistics as $D^2(P_N; A) = \frac{1}{N^2} \cdot \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \sum_{n=1}^{\infty} \frac{2n+1}{\pi A_n^2} \cdot P_n(\xi_i \cdot \xi_j)$ (Pycke’s statistic is the only one computed removing the elements with $i = j$ in the double sum over $i$ and $j$), and we have reported the values of $N \cdot D^2(P_N; A)$ in Table 1 along with the other values of interest. The values of the cumulative distribution function have been computed through $X_\nu$ and $X_\nu^*$, where $\nu = 1000$. The seven statistics yield similar results in the sense that all of them fail to reject the null hypothesis of uniformity, even if one of them (Giné’s statistic) comes very near to reject it at 90%. The respective error bounds are also displayed in parentheses. The difference in the bounds for the centered and the uncentered cases is eloquent. It should also be remarked that the bounds for the Cui-Freeden statistic are coherent with the rates of decrease derived in Remark 2 (iii).  

---

4In these computations, we do not consider s--energies since they cause some peculiar problems that will be dealt with in a separate paper.
Table 1. Computation of the test statistics on the data described in the text.

7. Proofs

In the following \( \omega (\cdot) \) will denote the uniform measure on the sphere \( \Omega \) and \( \omega^*(\cdot) := \omega (\cdot) / \omega (\Omega) \) the uniform probability measure corresponding to \( \omega (\cdot) \).

Proof of Theorem 4.1. We show that \( D^2 (P_N; A) \) is a degenerate \( V \)-statistic with respect to \( \omega (\cdot) \) (see [40], Chapter 5). Indeed, from the definition of the generalized discrepancy, it can be seen that

\[
N \cdot D^2 (P_N; A) = \frac{1}{N} \cdot \sum_{i=1}^{N} h (\xi_i, \xi_j)
\]

where \( h (\xi_i, \xi_j) = \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n (\xi_i \cdot \xi_j) \) is called the kernel. Since \( h (\xi_i, \xi_i) = \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \), we can write:

\[
N \cdot D^2 (P_N; A) = \frac{2}{N} \cdot \sum_{i=1}^{N} h (\xi_i, \xi_j) + \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2}.
\]

The first term is a \( U \)-statistic (see [40], Chapter 5). From the addition theorem of spherical harmonics, we have

\[
h (\xi_i, \xi_j) = \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n (\xi_i \cdot \xi_j)
\]

\[
= \sum_{n=1}^{\infty} \frac{1}{A_n^2} \cdot \sum_{k=-n}^{n} Y_{n,k} (\xi_i) \cdot Y_{n,k} (\xi_j),
\]

so that it is simple to see that \( \int_{\Omega} h (\eta, \xi) \omega^*(d\eta) = \int_{\Omega} \int_{\Omega} h (\eta, \xi) \omega^*(d\eta) \omega^*(d\xi) = 0 \). In this case the kernel is said to be degenerate. A very important role in this situation is played by the eigenvalues of the integral operator

\[
A m (\xi) = \int_{\Omega} h (\eta, \xi) m (\eta) \omega^*(d\eta).
\]

We can identify the eigenvalues of \( A \) with the sequence \( \{(\frac{1}{4\pi A_n^2})^{(2n+1)}; n \in \mathbb{N}\} \) where \( x^{\otimes i} \) means that \( x \) is repeated \( i \) times. The presence of the term \( (4\pi)^{-1} \) is due to the fact that the eigenvalues of \( A \) are defined with respect to the uniform measure on the sphere. The reason is very simple to see if \( A \) is invertible. Indeed, from the fact that the pseudodifferential operator \( A \) is invariant (see equation on p. 597 in [10]) and invertible, we get \( A^{-2} Y_n,j = A_n^{-2} \cdot Y_n,j, n = 0, 1, \ldots, j = -n, \ldots, n. \)

However, the eigenvalues of \( A \) are defined with respect to the probability measure \( \omega^* (\cdot) \), so that

\[
A Y_n,j = \frac{1}{\omega (\Omega)} \cdot A^{-2} Y_n,j = \frac{1}{4\pi A_n^2} \cdot Y_n,j.
\]

In all other cases (that is when \( A_n = +\infty \) for at least one value of \( n \in \mathbb{N} \)), the appearance of the \( (4\pi)^{-1} \) term is linked to the fact that the orthonormality of the eigenfunctions of the operator \( A \) are defined with respect to the probability measure \( \omega^* (\cdot) \), while the spherical harmonics are orthonormal with respect to the measure \( \omega (\cdot) \). In the following, the eigenvalues of \( A \), counted with their multiplicities and arranged in order of decreasing absolute value, will be denoted as \( \{\lambda_n; n \in \mathbb{N}\} \).

(i) We show that, if the points are uniformly distributed, then \( D (P_N; A) \) converges to 0. When \( E |h (\eta, \xi)| < \infty \), the strong law of large numbers holds for
\[D(P_N; A) \text{ (see [40] Theorem A, p. 190)} \] and \[D^2(P_N; A) \overset{a.s.}{\rightarrow} 0. \] But \[E|h(\eta, \xi)| = \sum_{n=1}^{\infty} \frac{2n + 1}{4\pi A_n^2} \cdot P_n(\eta \cdot \xi)\] and this is guaranteed by the condition \[\sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2} < \infty.\]

(ii) For degenerate U-statistics, the asymptotic distribution is given in [40, Theorem on p. 194]. Therefore, we get

\[N \cdot D^2(P_N; A) \overset{D}{\rightarrow} \sum_{n=1}^{\infty} \frac{1}{4\pi A_n^2} \cdot \sum_{k=-n}^{n} \left[ \chi_{n,k}^2(1) - 1 \right] + \sum_{n=1}^{\infty} \frac{2n + 1}{4\pi A_n^2}\]

where \(\{\chi_{n,k}^2(1) : n = 0, 1, \ldots; k = -n, \ldots, n\}\) is a sequence of independent chi-squared random variables with one degree of freedom. Using the classical relation

\[\sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2} \leq \infty\]

\[(7.1) \quad \gamma_s = E|h(\xi_i, \xi_j)|^s, \quad \gamma_{s,r} = E\{E[|h(\xi_i, \xi_j)|^s | \xi_i]\}^r.\]

We get

\[\gamma_2 = E|h(\xi_i, \xi_j)|^2 \leq \sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2}\]

and

\[\gamma_4 = E|h(\xi_i, \xi_j)|^4 \leq \left( \sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2} \right) \cdot \left( \sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2} \right)^2.\]

As concerns \(\gamma_{2,2}\), we use the relation \[\sum_{n=1}^{\infty} |Y_{n,j}(\xi)|^2 = \frac{2n + 1}{4\pi} \] to get

\[\gamma_{2,2} = E\left\{E\left[|h(\xi_i, \xi_j)|^2 | \xi_i\right]\right\}^2\]

\[= E\left\{\sum_{n=1}^{\infty} \frac{1}{A_n^4} \cdot \sum_{k=-n}^{n} |Y_{n,k}(\xi_i)|^2 \right\}^2\]

\[\times \left( \sum_{n=1}^{\infty} \frac{2n + 1}{A_n^2} \right)^2.\]
Proof of Theorem 5.1. We start with the uncentered case. Consider the following bound obtained through the inversion formula

\[ |\mathbb{P} \{ X \leq x \} - \mathbb{P} \{ X_\nu \leq x \}| \leq \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{|t|} \cdot \left| \phi_X(t) - \phi_{X_\nu}(t) \right| \, dt \]

\[ = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{|t|} \cdot \left| \phi_{X_\nu}(t) \right| \cdot \left| \frac{\phi_X(t)}{\phi_{X_\nu}(t)} - 1 \right| \, dt \]

\[ \leq \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{|t|} \cdot \left| \phi_{X_\nu}(t) \right| \cdot \left| E e^{it(X - X_\nu)} - 1 \right| \, dt \]

\[ \leq \frac{\sqrt{\mathbb{E} (X - X_\nu)^2}}{\pi} \cdot \int_{-\infty}^{\infty} \left| \phi_{X_\nu}(t) \right| \, dt \]

where the third step comes from the fact that \( X_\nu \) and \( X - X_\nu \) are independent and the fifth step from the inequalities \( |e^{it} - 1| \leq |t| \) and \( \mathbb{E} |X - X_\nu| \leq \sqrt{\mathbb{E} (X - X_\nu)^2} \) (see [42] Lemma 4.2, Chapter 13, p. 352, and [40] p. 197 for a similar majorization).

Then we have

\[ \phi_{X_\nu}(t) = \prod_{n=1}^{\nu} \left( 1 - \frac{2it}{4\pi A_n^2} \right)^{-\frac{2n+1}{4}} = \exp \left\{ -\sum_{n=1}^{\nu} \frac{2n+1}{2} \ln \left( 1 - \frac{it}{2\pi A_n^2} \right) \right\} \]

\[ = \exp \left\{ -\sum_{n=1}^{\nu} \frac{2n+1}{4} \ln \left( 1 + \frac{t^2}{4\pi^2 A_n^4} \right) \right\} \]

\[-i \sum_{n=1}^{\nu} \frac{2n+1}{2} \arctan \left( -\frac{t}{2\pi A_n^2} \right) \]

\[ = \exp \left\{ -\sum_{n=1}^{\nu} \frac{2n+1}{4} \ln \left( 1 + \frac{t^2}{4\pi^2 A_n^4} \right) \right\} \]

\[ \cdot \left\{ \cos \left[ \sum_{n=1}^{\nu} \frac{2n+1}{2} \arctan \left( -\frac{t}{2\pi A_n^2} \right) \right] \right\} \]

\[ -i \cdot \sin \left[ \sum_{n=1}^{\nu} \frac{2n+1}{2} \arctan \left( -\frac{t}{2\pi A_n^2} \right) \right] \]

\[ |\phi_{X_\nu}(t)| = \exp \left\{ -\sum_{n=1}^{\nu} \frac{2n+1}{4} \ln \left( 1 + \frac{t^2}{4\pi^2 A_n^4} \right) \right\} = \prod_{n=1}^{\nu} \left( 1 + \frac{t^2}{4\pi^2 A_n^4} \right)^{-\frac{2n+1}{4}} \]

\[ \leq \frac{1}{\prod_{n=1}^{\nu} \left( 1 + \frac{t^2}{4\pi^2 A_n^4} \right)^{\frac{2n+1}{4}}} \leq \frac{1}{\left( 1 + t^2 \cdot \sum_{n=1}^{\nu} \frac{2n+1}{12\pi^2 A_n^4} \right)^{\frac{3}{4}}} \]
and

\[
E (X - X_\nu)^2 = E \left( \sum_{n=\nu+1}^{\infty} \frac{\chi_n^2 (2n + 1)}{4 \pi A_n^2} \right)^2
\]

\[
= E \left( \sum_{n=\nu+1}^{\infty} \frac{\chi_n^2 (2n + 1)}{4 \pi A_n^2} - \sum_{n=\nu+1}^{\infty} \frac{2n + 1}{4 \pi A_n^2} \right) + \left( \sum_{n=\nu+1}^{\infty} \frac{2n + 1}{4 \pi A_n^2} \right)^2
\]

\[
= \sum_{n=\nu+1}^{\infty} \frac{1}{16 \pi^2 A_n^4} \cdot E \left( \chi_n^2 (2n + 1) - 2n - 1 \right)^2 + \left( \sum_{n=\nu+1}^{\infty} \frac{2n + 1}{4 \pi A_n^2} \right)^2
\]

\[
= \sum_{n=\nu+1}^{\infty} \frac{2 (2n + 1)}{16 \pi^2 A_n^4} + \left( \sum_{n=\nu+1}^{\infty} \frac{2n + 1}{4 \pi A_n^2} \right)^2.
\]

Therefore,

\[
|P \{X \leq x\} - P \{X_\nu \leq x\}| \leq \sqrt{2 \sum_{n=\nu+1}^{\infty} \frac{2n+1}{16 \pi^2 A_n^4} + \left( \sum_{n=\nu+1}^{\infty} \frac{2n+1}{4 \pi A_n^2} \right)^2} \cdot \int_{-\infty}^{+\infty} \frac{1}{1 + t^2 \cdot \frac{3}{4} \sum_{n=1}^{\nu} \frac{2n+1}{16 \pi^2 A_n^4}} \frac{dt}{\sqrt{t^2}}
\]

\[
= \frac{1}{\pi} \sqrt{\frac{2 \sum_{n=\nu+1}^{\infty} \frac{2n+1}{16 \pi^2 A_n^4} + \left( \sum_{n=\nu+1}^{\infty} \frac{2n+1}{4 \pi A_n^2} \right)^2}{3 \sum_{n=1}^{\nu} \frac{2n+1}{16 \pi^2 A_n^4}}} \cdot \frac{1}{\pi} \cdot \frac{1}{\pi} \cdot \int_{0}^{+\infty} \frac{1}{1 + \frac{z^2}{(1 + z)^{3/2}}} \frac{dz}{(1 + z)^{3/2}}
\]

where \(B\) is the beta function.

In the centered case, on the other hand, \(|\phi_{X_\nu} (t)|\) yields

\[
|\phi_{X_\nu} (t)| = |\phi_{X_\nu} (t)| = \frac{1}{\Pi_{n=1}^{\nu} \left( 1 + \frac{t^2}{4 \pi^2 A_n^4} \right) \frac{2n+1}{4} \sum_{n=2}^{\nu} \frac{2n+1}{20 \pi^2 A_n^4}}
\]

\[
\leq \frac{1}{\left( 1 + \frac{t^2}{4 \pi^2 A_n^4} \right)^{\frac{3}{2}} \left( 1 + t^2 \cdot \sum_{n=2}^{\nu} \frac{2n+1}{20 \pi^2 A_n^4} \right)^{\frac{3}{4}}}
\]

and \(|E e^{it(X - X_\nu)} - 1|\) becomes

\[
|E e^{it(X - X_\nu)} - 1| = \left| E e^{it(X - X_\nu)} - 1 - E it (X - X_\nu) \right|
\]

\[
\leq \left| E e^{it(X - X_\nu)} - 1 - it (X - X_\nu) \right|
\]

\[
\leq \frac{t^2 \cdot E |X - X_\nu|^2}{2}
\]
(always through Lemma 4.2, Chapter 13, p. 352) where
\[
\mathbb{E} (X - X_\nu^*)^2 = \mathbb{V} \left( \sum_{n=\nu+1}^{\infty} \frac{X_n^2 (2n+1)}{4\pi A_n^2} \right) = \sum_{n=\nu+1}^{\infty} \frac{2n+1}{8\pi^2 A_n^4}.
\]

Therefore,
\[
\| \mathbb{P} \{ X \leq x \} - \mathbb{P} \{ X_\nu^* \leq x \} \| \leq \frac{1}{\pi} \int_{-\infty}^{+\infty} \frac{1}{|t|} \cdot |\phi_X(t)| \cdot \mathbb{E} \left| e^{it(X - X_\nu^*)} - 1 \right| dt
\]
\[
\leq \frac{2}{\pi} \mathbb{E} \left| X - X_\nu^* \right|^2 \cdot \int_{0}^{+\infty} \frac{t}{\left( 1 + t^2 \cdot \frac{4}{5} \sum_{n=2}^{\nu} \frac{2n+1}{16\pi^2 A_n^4} \right)^{\frac{3}{2}}} dt
\]
\[
= \sum_{n=\nu+1}^{\infty} \frac{2n+1}{16\pi^2 A_n^4} \cdot \frac{5}{4\pi} \cdot B \left( 1, \frac{1}{4} \right).
\]

The other relations are obvious from \( A_n^{-1} \sim k \cdot n^{-1-\alpha} \), using the fact that
\[
\mathbb{E} \left[ \sum_{n=1}^{\infty} \frac{2n+1}{4\pi A_n^2} \cdot P_n (\xi_i \cdot \xi_j) \right]^2 = \sum_{n=1}^{\infty} \frac{2n+1}{16\pi^2 A_n^4}.
\]

\[\square\]
